# Derivative of functions in the form $ax^n$

Derivative of functions in the form  $ax^n$

$$f(x) = ax^n \longrightarrow f'(x) = anx^{n-1} \quad \text{or} \quad \frac{dy}{dx} = anx^{n-1}$$

For example:

$$f(x) = ax^n$$

$$f'(x) = anx^{n-1}$$

If

$$f(x) = 2x^5$$

$$f'(x) = (2)(5)x^{5-1} = 10x^4$$

If

$$f(x) = 3x$$

$$f'(x) = (3)(1)x^{1-1} = 3x^0 = 3$$

If

$$f(x) = 5x^2$$

$$f'(x) = (5)(2)x^{2-1} = 10x^1 = 10x$$

If

$$f(x) = 4x^3$$

$$f'(x) = (4)(3)x^{3-1} = 12x^2$$

For any term  $x$   
except 0 ,  
 $x^0=1$

## Derivative of functions in the form $ax^n$

The derivative of a constant is zero.

$$f(x) = a \longrightarrow f'(x) = 0$$

For example:

$$\text{If } f(x) = 2 \longrightarrow f'(x) = 0$$

$$\text{If } f(x) = \frac{1}{2} \longrightarrow f'(x) = 0$$

# Sum Rule

The sum rule for derivatives states that the derivative of a sum is equal to the sum of the derivatives.

$$f(x) = g(x) + h(x) \longrightarrow f'(x) = g'(x) + h'(x)$$

For example:

$$\text{If } f(x) = 3x^2 - x + \frac{1}{2} \text{ find } \frac{dy}{dx}.$$

$$f'(x) = 3 \times 2 \times x^{2-1} - 1 \times 1 \times x^{1-1} + 0$$

$$f'(x) = 6x - 1 + 0$$

$$= 6x - 1$$

# Second derivative

The second derivative ( $f''$  or  $\frac{d^2y}{dx^2}$ ), is the derivative of the derivative ( $f'$  or  $\frac{dy}{dx}$ ).

To find the second derivative:

- 1 Find the  $f'(x)$ .
- 2 Find derivative of the  $f'(x)$ .

For example:

$$\text{If } f(x) = 4x^3 - x + \frac{1}{2} \text{ find } \frac{d^2y}{dx^2}.$$

Step 1   $\frac{dy}{dx} = f'(x) = 4 \times 3 \times x^{3-1} - 1 + 0 = 12x^2 - 1$

Step 2   $\frac{d^2y}{dx^2} = f''(x) = 12 \times 2 \times x^{2-1} - 0 = 24x$

## Gradient at a point on a curve by derivative

The gradient at a point on a curve is defined as the gradient of the tangent to the curve at that point.

The derivative function  $f'(x)$  gives the gradient (slope) of the tangent to the curve  $f(x)$  at any point  $x$ .

To find the gradient of a curve at a point on the curve:

- 1 Find the  $f'(x)$ .
- 2 Substitute the  $x$  in the  $f'(x)$  with the  $x$ -coordinate of the point.

For example:

Calculate the gradient of the curve  $y = x^3 + 9x + 1$  at  $x = -2$ .

Step 1

$$\begin{aligned} f'(x) &= 1 \times 3 \times x^{3-1} + 9 \times 1 \times x^{1-1} + 0 \\ &= 3x^2 + 9 \end{aligned}$$

Step 2

The gradient of the curve at  $x = -2$  is  $f'(-2)$

$$\begin{aligned} f'(-2) &= 3(-2)^2 + 9 \\ &= 12 + 9 = 21 \end{aligned}$$

## Coordinates of the stationary points

To find the coordinate of the stationary points:

- 1 Find the  $f'(x)$ .
- 2 Solve the equation  $f'(x) = 0$
- 3 Substitute  $x$  in the function equation by the values of the found  $x$ -coordinate

For example: A curve has equation  $y = 2x^3 - 3x^2 - 5$ .  
Find the coordinates of the two stationary points on the curve.

Step 1

$$f'(x) = 6x^2 - 6x$$

Step 2

$$f'(x) = 0 \implies 6x^2 - 6x = 0$$

$$6x(x - 1) = 0$$

$$\begin{array}{l} \longrightarrow 6x = 0 \quad x = 0 \\ \longrightarrow x - 1 = 0 \quad x = 1 \end{array}$$

Step 3

$$y = 2x^3 - 3x^2 - 5 \longrightarrow y = 2(0)^3 - 3(0)^2 - 5 \quad y = -5$$

$$y = 2x^3 - 3x^2 - 5 \longrightarrow y = 2(1)^3 - 3(1)^2 - 5 \quad y = -6$$

The coordinates of the two stationary points are  $(0, -5)$  and  $(1, -6)$ .

## Type of stationary point (turning point)

A **turning point** is a point at which the derivative changes sign. (a curve **changes** from **moving upwards** to **moving downwards**, or vice versa )

A turning point may be either a relative maximum or a relative minimum. (also known as local minimum and maximum).

If the function is differentiable, then a turning point is a stationary point; however, not all stationary points are turning points.

To find the type of stationary point (local maximum - local minimum):

1

Find the coordinates of the stationary points.

2

Substitute the  $x$ -coordinate of the stationary points in the second derivative.

I. If  $f''(x) < 0$ , it is a local maximum. (**turning point**)

II. If  $f''(x) > 0$ , it is a local minimum. (**turning point**)

III. If  $f''(x) = 0$ , it is not a local minimum or maximum. (inflection)

**Turning point**  
Local maximum  
stationary point

$$f''(x) < 0$$

stationary point  
Local minimum  
**Turning point**

$$f''(x) > 0$$

stationary point  
it is not a local  
minimum or maximum

$$f''(x) = 0$$

### Example

Find the coordinates of the turning points of the graph  $y = x^3 + 3x^2 - 6$ .

To find the  $x$ -coordinates of the stationary points:

Step 1  $f'(x) = 3x^2 + 6x$

Step 2  $f'(x) = 0$        $3x^2 + 6x = 0$        $3x(x + 2) = 0$   $\left\{ \begin{array}{l} \rightarrow 3x = 0 \quad x = 0 \\ \rightarrow x + 2 = 0 \quad x = -2 \end{array} \right.$  stationary points

To find the type of stationary point (local maximum - local minimum):

Step 1  $f''(x) = 6x + 6$

Step 2  $f''(0) = 6(0) + 6 = 6 > 0$  Local minimum  $(0, -6)$

$$f(0) = (0)^3 + 3(0)^2 - 6 = -6$$

$f''(-2) = 6(-2) + 6 = -6 < 0$  Local maximum  $(-2, -2)$

$$f(-2) = (-2)^3 + 3(-2)^2 - 6 = -2$$
